## Intro to Image Processing

- MathWork's Matlab product:

The Image Processing Toolbox

- Applications in computer vision, motion analysis, biometrics
- Segmentation \& edge-finding

Dr. Lai's mission for us:
Find the boundaries of similarly patterned areas in noisy pictures and output them for denoising by spline triangulations.

## Common techniques for segmentation

- Histogram-based
- Clusters
- Region-growing

Gradient-based regions
Contrast peaks and valleys

All such techniques are not directly intended to be used in noised-and-denoised images.

The Berkeley Segmentation Engine

## Whereas we are dealing with this:

## What's the best way to find significant regions in a noisy image?

## Image requires additional cleaning

Boundary point-collecting

- Crawling (edge-finding)
- Box-centers (region-growing)
- Iterating over both black and white thresholded images

Remove redundancy in boundary chains
Remove isolated points
Order the boundary points

## First attempt - Edge crawling

```
function [X,Y]=hasNeighbor(A, D, X, Y, C1, C2)
    * hasNeighbor takes a binary matrix A and an ordered vector of
    * points around the current point in the crawl.
    S=size(A);
    * default X, Y vals in case no neighbor is found
    X=[x]; Y=[Y];
    test=0; % breakout value
    * check for black points in list of D coardinates
    for c=1: length(D)
    *index-out-of-bounds test
    if (D(1,C)<1 || D (1,C)>S(2) || D (2,C)<1 || D (2,C)>S(1))
            ;
        else
            if A(D (2,C),D(1, C))>1
                test=1;
                for i=1:length(C1) %loop checks for hitting previous point
                    if (C1(i)==D(1,C) && C2(i)==D(2,C))
                                    test=0; % prevent breakout, point has already been found
                    end
                    end
                if (test==1) % not a repeated point
                    X=[X, D(1,C)]; % store coordinates
                    Y=[Y,
            end
        end
        end
    end
```

Enmeshedness, recalculating slope, forking directions; it was generally a mess.

## Trial and error - Edge-crawling

## Trial and error - Cleaning the image

Thinning

- How?
- How much?

Setting thresholds

- Handpicked
- Automatic
- Both black and white thresholds
"Compressing" each $5 \times 5$ macropixel
- Identifying solely white areas of the image
- Form regions from these adjacent white areas

Original Lena image

Noised, then denoised Lena

Lena after thresholding

"Compressed" image of box centers

"Compressed" image of box centers (inverted)

## What do we do with these?

Clearly we use these to find the boundaries of the white areas.
We programmed an unseeded region-growing method, where we iterate through every white pixel in the compressed image, initiating a crawl for other white neighbors.

## Removing redundancies

```
1 function C = cleanChains(C)
6 -
7-
8-
9-
10 -
11 -
12 -
13 -
14 -
15 -
16 -
17-
18 -
19 -
20-
21-
```

```
2 % removes redundancy in each chain of cell array C
```

2 % removes redundancy in each chain of cell array C
3- Schain=size(C);
3- Schain=size(C);
4- for i=1:Schain(2)
4- for i=1:Schain(2)
5- chain=C{i};
5- chain=C{i};

```
        S=size(chain); count=1;
```

        S=size(chain); count=1;
        while(count<=S(2))
        while(count<=S(2))
            J=find(chain(1,:)==chain(1,count) & chain(2,:)==chain(2, count));
            J=find(chain(1,:)==chain(1,count) & chain(2,:)==chain(2, count));
            j=2;
            j=2;
            while (j <= length(J))
            while (j <= length(J))
                chain(:,J(j))=[0; 0];
                chain(:,J(j))=[0; 0];
                j=j+1;
                j=j+1;
            end
            end
            c1=nonzeros(chain(1,:));
            c1=nonzeros(chain(1,:));
            c2=nonzeros(chain(2,:));
            c2=nonzeros(chain(2,:));
            chain=[c1'; c2'];
            chain=[c1'; c2'];
            count=count+1;
            count=count+1;
            S=size(chain);
            S=size(chain);
        end
        end
        C{i}=chain;
        C{i}=chain;
    end
    ```
    end
```

First step of the chain-aggregating process

## Clean isolated points from the chains

```
1 function E=removeIsolatedPoints(C)
* remove isolated boumdery points in Each Ghain 口f
* the cell array C
    S=size{C!:
    E=cell(1,S(2));
    Ior i=1:S\2!
        ChEin=C{i}:
        SChain=size{Ohain):
        for j=1:SChain{2)
            ix {hasNeighbors{chain, chain{:,j!) <= 1!
                Ohain!:, j)=[0;0]:
            End
        Encl
        ci=nonzeros{chain\1, :!);
        CZ=nonzeros{ohain{2,:\);
        E{i}=[c1'; [2'];
        End
```

If a point has one or no white neighbors, it's irrelevant.

## Ordering of boundary points

```
function finalChain=orclerChain2 (chain)
```

function finalChain=orclerChain2 (chain)

* orders the closed boundary coordinates of each cell
* orders the closed boundary coordinates of each cell
* in the cell array 'chain'
* in the cell array 'chain'
cells=1: SC=size(chain): finalChain={);
cells=1: SC=size(chain): finalChain={);
while (cells <= SC(2))
while (cells <= SC(2))
C=chain(cells);
C=chain(cells);
orderedChain=C{:,1);
orderedChain=C{:,1);
initFoint=C{:,1):
initFoint=C{:,1):
point=[-1;-1];
point=[-1;-1];
count=1;
count=1;
alreadyChecked=initPoint; * for backtracking
alreadyChecked=initPoint; * for backtracking
SChain=size(C);
SChain=size(C);
while {count < SChain(Z)}
while {count < SChain(Z)}
if {count==1)
if {count==1)

\hline 14 & - & \(\mathrm{C}=\) thinchain: \\
\hline
\end{tabular}

We look at every other point (representing a five-by-five section of the image) in the chain in order to make the triangulation process faster.

Resulting regions from both thresholds

Resulting regions

\section*{Demonstration of our method on \(F\)-16 photo, extra-noisy Lena}

\section*{What more can be done}
- Better thresholds (completely automatic)
- Better clean
- Circles, as opposed to blocks
- Different block size
- Color images
- 3-dimensions

\section*{Who is it?}

Thank you, Dr. Lai!
